Transaction Processing (ii)

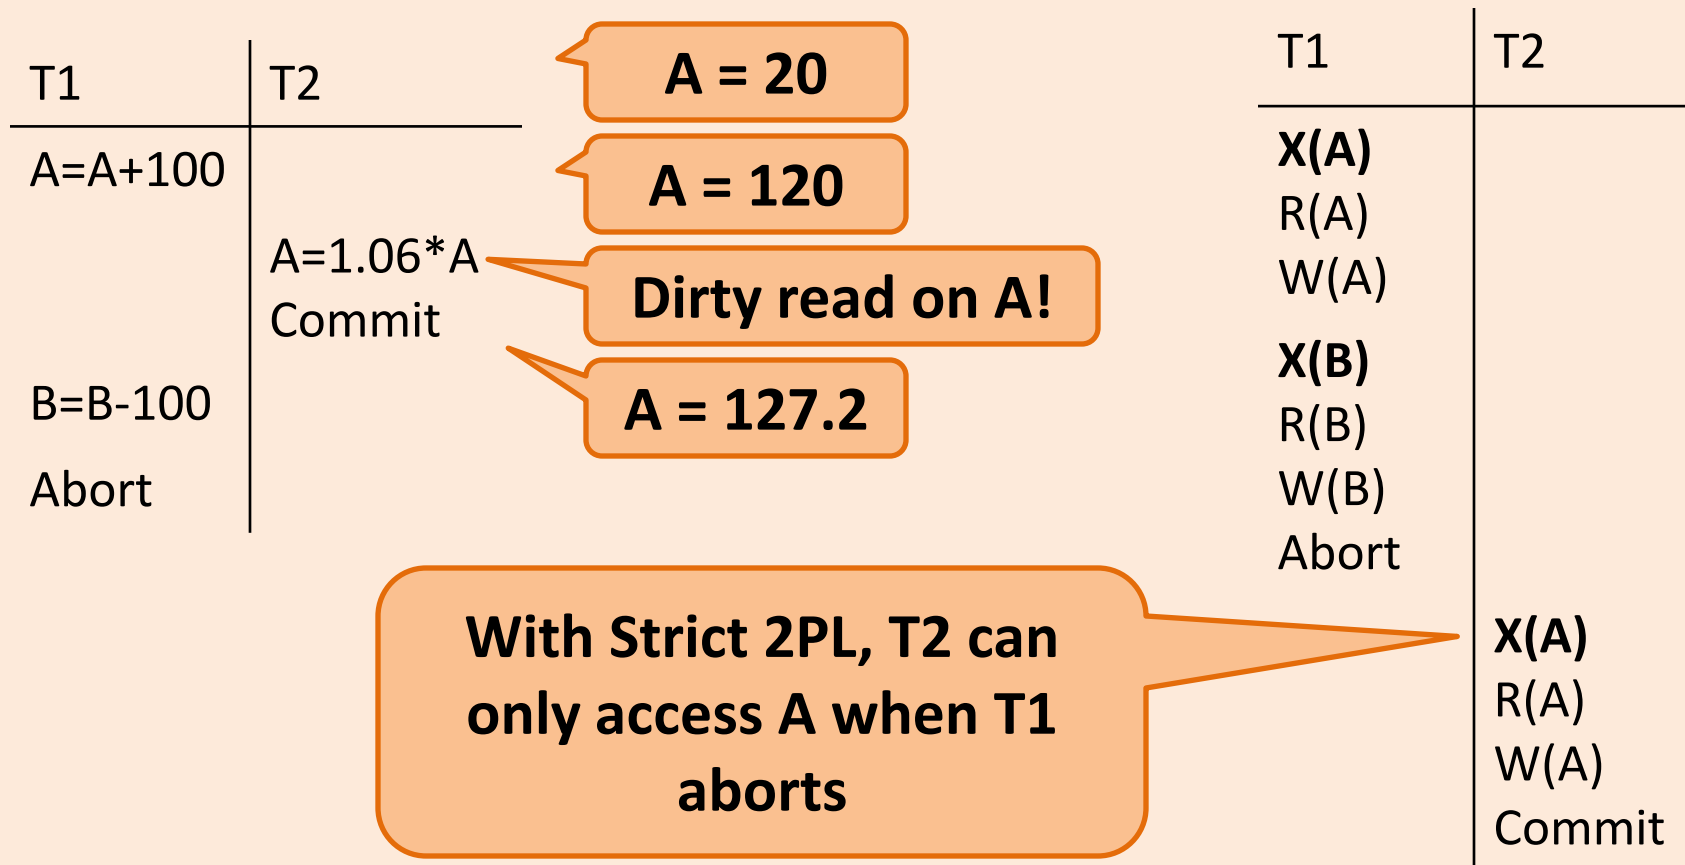

Asst. Prof. Lipyeow Lim
Information & Computer Science Department
University of Hawaii at Manoa

Lock-based Concurrency Control

- Strict Two-phase Locking (Strict 2PL) Protocol:
 - Each Xact must obtain a *S (shared)* lock on object before reading, and an *X (exclusive)* lock on object before writing.
 - All locks held by a transaction are released when the transaction completes
 - *(Non-strict) 2PL Variant:* Release locks anytime, but cannot acquire locks after releasing any lock.
 - If an Xact holds an X lock on an object, no other Xact can get a lock (S or X) on that object.
- Strict 2PL allows only serializable schedules.
 - Additionally, it simplifies transaction aborts
 - *(Non-strict) 2PL* also allows only serializable schedules, but involves more complex abort processing

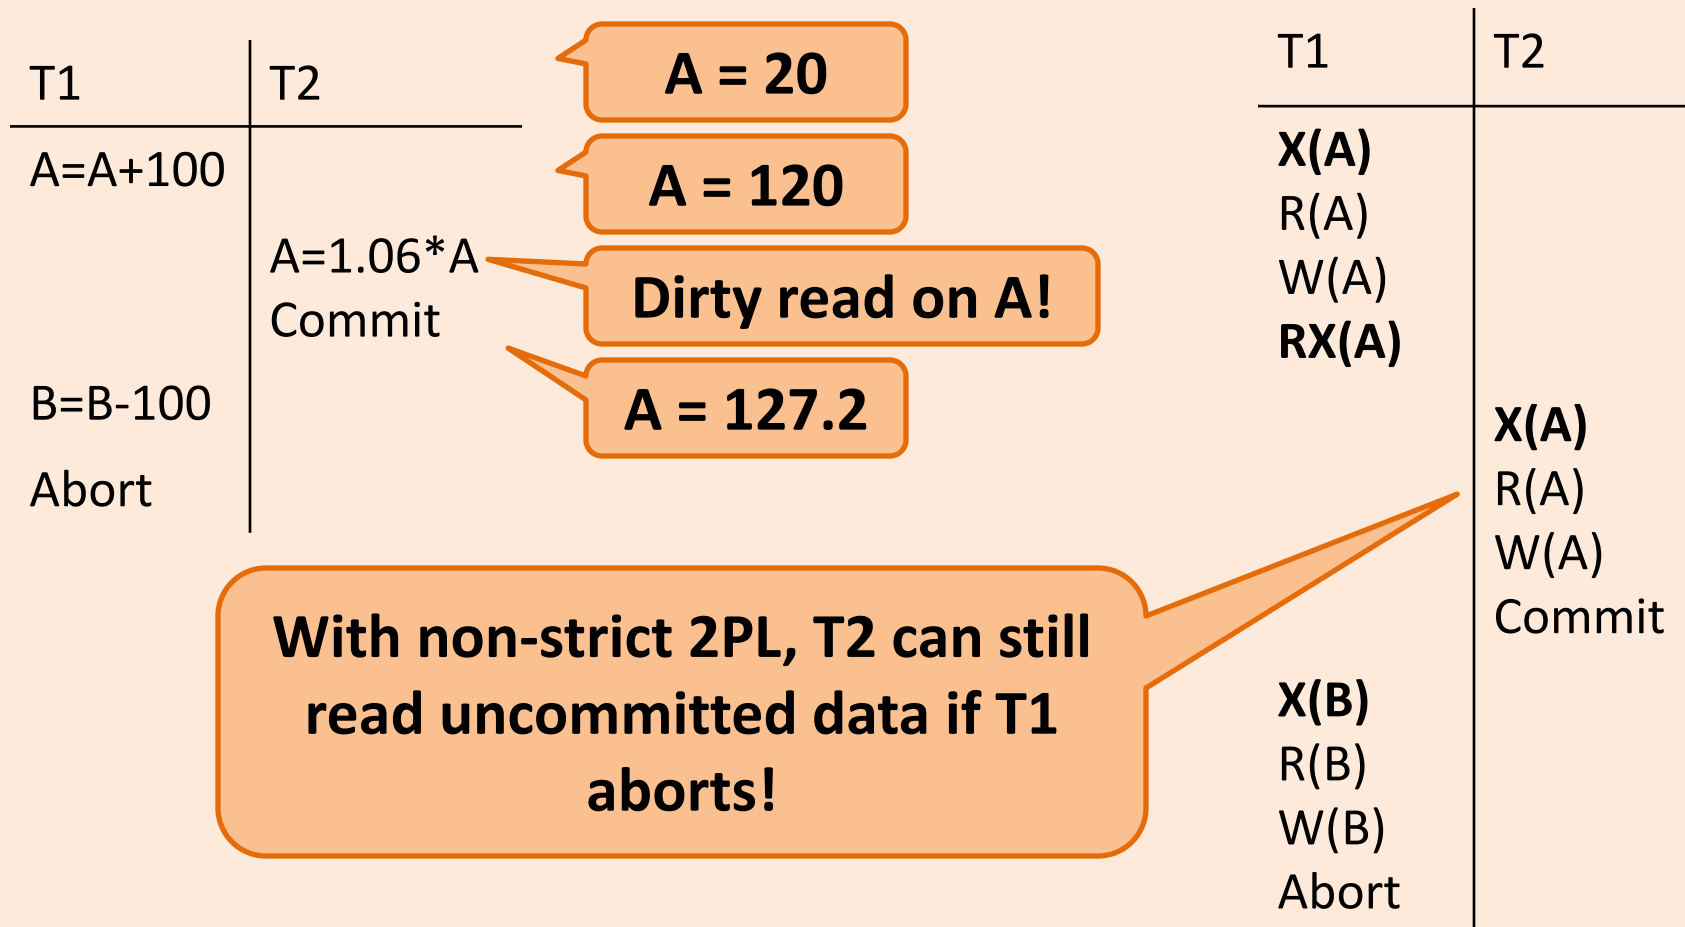

Example (Strict 2PL)

- Consider the dirty read schedule

Example (Non-Strict 2PL)

- Consider the dirty read schedule

Deadlocks

- Cycle of transactions waiting for locks to be released
- DBMS has to either prevent or resolve deadlocks
- Common approach:
 - Detect via timeout
 - Resolve by aborting transactions

T1	T2
Req X(A)	Req X(B)
Gets X(A)	Gets X(B)
...
Req X(B)	Req X(A)

Aborting a Transaction

- If a transaction $T1$ is aborted, all its actions have to be undone.
 - Not only that, if $T2$ reads an object last written by $T1$, $T2$ must be aborted as well!
- Most systems avoid such *cascading aborts* by releasing a transaction's locks only at commit time.
 - If $T1$ writes an object, $T2$ can read this only after $T1$ commits.
- In order to *undo* the actions of an aborted transaction, the DBMS maintains a *log* in which every write is recorded.
 - This mechanism is also used to recover from system crashes: all active Xacts at the time of the crash are aborted when the system comes back up

Lock Granularity

- What should the DBMS lock ?
 - Row ?
 - Page ?
 - A Table ?

```
UPDATE Sailors
SET      rating=0
WHERE    rating>9
```

```
SELECT *
FROM    Sailors
```

```
SELECT *
FROM    Sailors
WHERE   rating < 2
```

```
UPDATE Boats
SET      color='red'
WHERE    bid=13
```

```
UPDATE Boats
SET      color='blue'
WHERE    bid=100
```

Crash Recovery

- **Transaction Manager:** DBMS component that controls execution (eg. managing locks).
- **Recovery Manager:** DBMS component for ensuring
 - Atomicity: undo actions of transactions that do not commit
 - Durability: committed transactions survive system crashed and media failures
- Assume atomic writes to disk.

The Log

- The following actions are recorded in the log:
 - *Ti writes an object*: the old value and the new value.
 - Log record must go to disk before the changed page! (Write Ahead Log property)
 - *Ti commits/aborts*: a log record indicating this action.
- Log records are chained together by Xact id, so it's easy to undo a specific Xact.
- Log is often *duplexed* and *archived* on stable storage.
- All log related activities (and in fact, all CC related activities such as lock/unlock, dealing with deadlocks etc.) are handled transparently by the DBMS.

Recovering from a Crash

- There are 3 phases in the *Aries* recovery algorithm:
 - Analysis: Scan the log forward (from the most recent *checkpoint*) to identify all Xacts that were active, and all dirty pages in the buffer pool at the time of the crash.
 - Redo: Redoes all updates to dirty pages in the buffer pool, as needed, to ensure that all logged updates are in fact carried out and written to disk.
 - Undo: The writes of all Xacts that were active at the crash are undone (by restoring the *before value* of the update, which is in the log record for the update), working backwards in the log. (Some care must be taken to handle the case of a crash occurring during the recovery process!)
