# ICS 321 Data Storage & Retrieval Overview of Query Processing

Prof. Lipyeow Lim
Information & Computer Science Department
University of Hawaii at Manoa

# **Query Processing**

- Query Execution Plan (QEP): tree of database operators.
  - At high-level, relational algebra operators are used
  - At low-level, RA operators with particular implementation algorithm.
- Plan enumeration: find equivalent plans
  - Different QEPs that return the same results
  - Query rewriting: transformation of one QEP to another equivalent QEP.
- Cost estimation: a mapping of a QEP to a cost
  - Cost Model: a model of what counts in the cost estimate. Eg. Disk accesses, CPU cost ...
- Query Optimizer:
  - Explores the space of equivalent plan for a query
  - Chooses the best plan according to a cost model

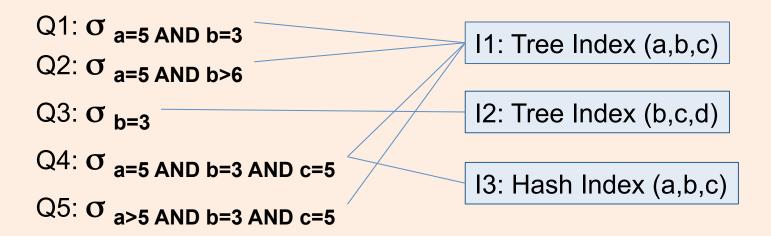

### Query Execution Plans

- A tree of database operators: each operator is a RA operator with specific implementation
- Selection  $\sigma$ : Index Scan or Table Scan
- Projection  $\pi$ :
  - Without DISTINCT: Table Scan
  - With DISTINCT : requires sorting or index scan
- Join ⋈ :
  - Nested loop joins (naïve)
  - Index nested loop joins
  - Sort merge joins

# **Enumerating Plans: Access Paths**

- An <u>access path</u> is a method of retrieving tuples. Eg. Given a query with a selection condition:
  - File or table scan
  - Index scan
- Index matching problem: given a selection condition, which indexes can be used for the selection, i.e., matches the selection?
  - Selection condition normalized to conjunctive normal form (CNF), where each term is a conjunct
  - Eg. (day<8/9/94 AND rname='Paul') OR bid=5 OR sid=3</p>
  - CNF: (day<8/9/94 OR bid=5 OR sid=3 ) AND (rname='Paul' OR bid=5 OR sid=3)</p>

# **Index Matching**

- A tree index matches a selection condition if the selection condition is a prefix of the index search key.
- A hash index matches a selection condition if the selection condition has a term attribute=value for every attribute in the index search key

### One Approach to Selections

- 1. Find the most selective access path, retrieve tuples using it
- 2. Apply remaining terms in selection not matched by the chosen access path
- The <u>selectivity</u> of an access path is the size of the result set (in terms of tuples or pages).
  - Sometimes selectivity is also used to mean <u>reduction</u> <u>factor</u>: fraction of tuples in a table retrieved by the access path or selection condition.
- Eg. Consider the selection: day<8/9/94 AND bid=5 AND sid=3</li>
  - Tree Index(day)
  - Hash index (bid,sid)

#### **Nested Loop Join**

S1	<u>sid</u>	sname	rating	age
	22	Dustin	7	45.0
	31	Lubber	8	55.5
	58	Rusty	10	35.0

M

```
        R1
        sid
        bid
        day

        22
        101
        10/10/96

        58
        103
        11/12/96
```

```
For each data page P_{S1} of S1

For each tuple s in P_{S1}

For each data page P_{R1} of R1

For each tuple r in P_{R1}

if (s.sid==r.sid)

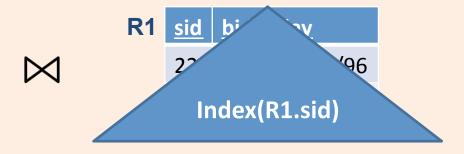

then output s,r
```

Worst case number of disk reads

= Npages(S1) + |S1|\*Npages(R1)

# Index Nested Loop Join

S1	<u>sid</u>	sname	rating	age
	22	Dustin	7	45.0
	31	Lubber	8	55.5
	58	Rusty	10	35.0

```
For each data page P_{s1} of S1
For each tuple s in P_{s1}
if (s.sid \in Index(R1.sid))
then fetch r & output <s,r>
```

- Worst case number of disk reads with tree index
  - = Npages(S1) +  $|S1|*(1 + log_F Npages(R1))$
- Worst case number of disk reads with hash index
  - = Npages(S1) + |S1|\*2

#### Sort Merge Join

<b>S</b> 1	sid	sname	rating	200	R1	<u>sid</u>	<u>bid</u>	day
01					IXI	19	100	8/8/99
	22	Dustin	/	45.0		22	101	10/10/96
	31	Lubber	8	55.5				
	58	Rusty	10	35.0		22	99	10/12/95
	50	Rasty	10	33.0		58	103	11/12/96

- 1. Sort S1 on SID
- 2. Sort R1 on SID
- 3. Compute join on SID using Merging algorithm
- If join attributes are relatively unique, the number of disk pages
  - = Npages(S1) log Npages(S1)
  - + Npages(R1) log Npages(R1)
  - + Npages(S1) + Npages(R1)
- What if the number of duplicates is large?
  - the number of disk pages approaches that of nested loop join.

# Example

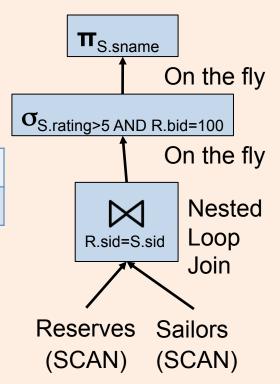

**SELECT** S.sname

**FROM** Reserves R, Sailors S

WHERE R.sid=S.sid AND R.bid=100 AND S.rating>5

Reserves	40 bytes/tuple	100 tuples/page	1000 pages
Sailors	50 bytes/tuple	80 tuples/page	500 pages

- Nested Loop Join cost 1K+ 100K\*500
- On the fly selection and project does not incur any disk access.
- Total disk access = 500001K (worst case)

# Example: Predicate Pushdown

**SELECT** S.sname

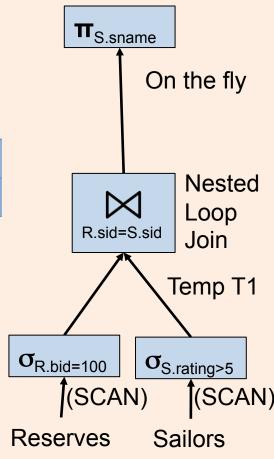

**FROM** Reserves R, Sailors S

10%

WHERE R.sid=S.sid AND R.bid=100 AND S.rating>5

Reserves	40 bytes/tuple	100 tuples/page	1000 pages
Sailors	50 bytes/tuple	80 tuples/page	500 pages

- Nested Loop Join requires materializing the inner table as T1.
- With 50% selectivity, T1 has 250 pages
- With 10% selectivity, outer "table" in join has 10K tuples
- Disk accesses for scans = 1000 + 500
- Writing T1 = 250
- NLJoin = 10K \* 250
- Total disk access = 2500.175 K (worst case)

What happens if we make the left leg the inner table of the join?

# Example: Sort Merge Join

**SELECT** S.sname

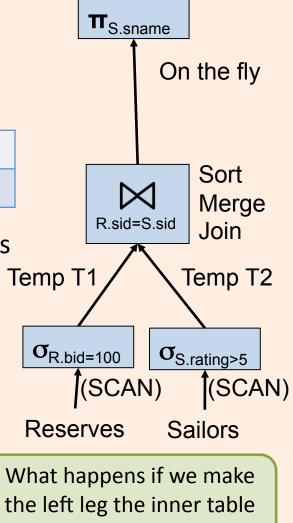

**FROM** Reserves R, Sailors S

10% 50%

WHERE R.sid=S.sid AND R.bid=100 AND S.rating>5

Reserves	40 bytes/tuple	100 tuples/page	1000 pages
Sailors	50 bytes/tuple	80 tuples/page	500 pages

- Sort Merge Join requires materializing both legs for sorting.
- With 10% selectivity, T1 has 100 pages
- With 50% selectivity, T2 has 250 pages
- Disk accesses for scans = 1000 + 500
- Writing T1 & T2 = 100 + 250
- Sort Merge Join = 100 log 100 + 250 log 250 + 100+250 (assume 10 way merge sort)
- Total disk access = 52.8 K

of the join?

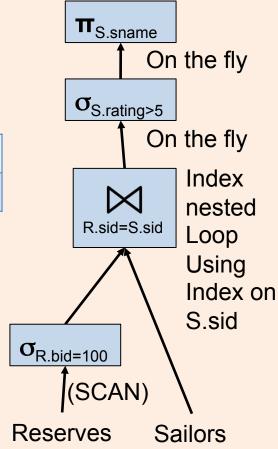

# Example: Index Nested Loop Join

SELECT S.sname
FROM Reserves R, Sailors S

WHERE R.sid=S.sid AND R.bid=100 AND S.rating>5

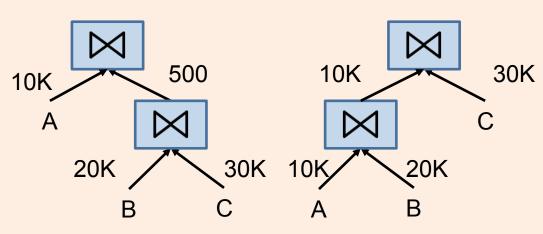

Reserves	40 bytes/tuple	100 tuples/page	1000 pages
Sailors	50 bytes/tuple	80 tuples/page	500 pages

- With 10% selectivity, selection on R has 10K tuples
- Disk accesses for scan = 1000
- Index Nested Loop Join = 10K\*(1
  - $+ \log_{10} 500) = 37K$
- Total disk access = 38 K

What happens if we make the left leg the inner table of the join?

# Join Ordering

Relations	Tuples	Pages
А	10K	1000
В	20K	2000
С	30K	3000
A join B	10K	1000
B join C	1K	100

- Independent of what join algorithm is chosen, the order in which joins are perform affects the performance.
- Rule of thumb: do the most "selective" join first
- In practice, left deep trees (eg. the right one above) are preferred --- why?

#### Statistics & Cost Estimation

- Page size
- Data Statistics:
  - Record size -> number of records per data page
  - Cardinality of relations (including temporary tables)
  - Selectivity of selection operator on different columns of a relation
- (Tree) Index Statistics
  - number of leaf pages, index entries
  - Height
- Statistics collection is user triggered
  - DB2: RUNSTATS ON TABLE mytable AND INDEXES ALL
  - Oracle: analyze table command or dbms\_stats package
